

Station 4: Filtering & Water Flow

How do different sized particles affect water flow?

Procedure:

Test 1 - Sand:

1. Place coffee filter in the stand
2. Put sand in the filter
3. Pour water slowly and observe the flow
4. Record: How fast does water pass through?

Test 2 - Little Rocks:

1. Empty and replace filter
2. Put little rocks in the filter
3. Pour water slowly and observe
4. Record: What happens to the water flow?

Test 3 - Bigger Rocks:

1. Empty and replace filter
2. Put bigger rocks in the filter
3. Pour water slowly and observe
4. Record: Compare to sand and little rocks

Record in Your Journal:

- Which material let water flow fastest?
- Which material slowed water the most?
- Draw what you observed in each test
- Why do you think particle size affects water flow?

Real World: This is how water filters work! Smaller particles create barriers that slow water, while larger particles let water flow through faster. This is why we use different sized materials in water treatment systems.
